Not : Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

## Description

### Field of the Invention

[0001] This invention relates to a fluid distributor for mass transfer columns, and more particularly, to liquid distributors for a gas-liquid contact column with at least one baffle which enhances liquid mixing.

### Background of the Invention

[0002] Mass transfer columns such as liquid-vapor contact columns are employed for example in distillation, absorption and stripping procedures. Generally, a column contains one or more liquid-vapor contacting zones which can comprise packing material to effect efficient contact between the upwardly flowing gas and the downwardly flowing liquid.

[0003] Efficient liquid distribution to a packed bed requires a uniform composition and flow profile to be delivered over the entire packing surface. A collector/distributor arrangement is typically employed to achieve such liquid distribution. If this is not achieved then the distributor arrangement is essentially causing liquid maldistribution and the packing will not perform optimally. Such liquid maldistribution results in a greater height requirement of the packed bed necessary to effect a given amount of mass transfer.

[0004] Where the packing is arranged so that there is more than one liquid-vapor contacting zone or bed, the liquid typically is redistributed between the packing of one bed and that of another bed. Effective redistribution accomplishes: 1) mixing the liquid to smooth composition profiles that may have developed in the bed above and 2) providing good initial distribution to the bed below. A collector/distributor combination is normally used for redistribution in a packed column. A collector is a device that captures liquid from the packing above, and from possible feed locations, and directs the liquid to a small number of downcomers. These downcomers direct the liquid onto the distributor. The distributor contains a plurality of orifices through which liquid streams fall onto the packing. However, the use of a collector increases column height and thus increases capital cost.

[0005] There are several types of liquid distributors for packed columns. Of these types, the pan distributor may be used as a liquid collector. This is because 1) the gas risers through which the upwardly flowing vapor passes are covered by "hats" which deflect liquid falling on top of them and 2) the distributor floor is sealingly closed to the interior of the column shell. The net effect is that all liquid is collected in the liquid pool held up on the pan, and cannot fall directly through to the liquid-vapor contacting zone below. Thus, some mixing of liquid occurs before it leaves the distributor. Where a liquid feed is introduced to a column, that feed may be sparged directly onto the distributor.

[0006] Pan distributor arrangements without a collector are significantly cheaper than when a collector is used because the cost of making and installing the collector is removed along with the additional column height required to house it. However, there are potential performance drawbacks associated with eliminating a collector. As previously stated, a primary function of a distributor is to deliver a liquid of uniform composition. If the liquid falling onto the distributor has a composition profile, then without a collector, there is no guarantee of uniform mixing on the distributor pan itself. Also, there is a concern about distribution quality due to inertial effects associated with liquid impinging directly onto the liquid held up on the distributor, particularly with an external liquid feed as may occur at a feed point. This may cause variation in the flow through the perforations in the distributor floor, thus decreasing the distribution quality.

[0007] The prior art has attempted to compensate for these potential inefficiencies, when a distributor is employed without a collector, by a variety of distributor constructions. For example, U.S. Patent No. 5,132,055 discloses a distributor with U-shaped sections encompassing liquid spaces and a peripheral channel communicating with the liquid spaces. An embodiment of this reference discloses having 2 plates mounted in each liquid space. Other variations of this embodiment are also disclosed. However, all of the arrangements disclosed in this reference are specific to a distributor having channels with vertical walls and the plates are mounted within each individual channel. Each channel runs in the same direction across the distributor and therefore does not effectively promote mixing in every direction. Even though the channels are connected by a peripheral channel this is still insufficient to accomplish uniform mixing across the entire cross section of the distributor.

[0008] U.S. Patent No. 5,240,652 discloses the use of a liquid collector and liquid distributor where the distributor contains a trough below the level of the vapor risers. One embodiment of the '652 reference adds a deflector plate between the trough and the distributor. However, the mixing of the liquid for proper redistribution still requires the use of the collector in this reference and thus would still incur the additional cost for the required column height to accommodate the collector.

[0009] Another reference, U.S. Patent No. 5,158,713 teaches a distributor arrangement for the mixing of liquid without the need for a collector. In this particular arrangement two or more duct-like troughs are placed above the liquid level in the distributor. The troughs are constructed with one closed end and at least one opening at the other end. Liquid that flows along the trough flows through the opening to the liquid accumulated above the distributor. The reference does not provide for mixing of the liquid that directly impinges on the distributor through the spaces between troughs. Further, there is no flow dampening of drops impinging directly on the distributor. The device is complex and may re-

quire additional column height to allow for the troughs to be suspended above the liquid level and thus, could also be costly.

[0010] Mixing of vapor in a column is the focus of U. S. Patent No. 5,145,612. In this reference, mixing is achieved by limiting the number of vapor risers in the distributor and adding a mixing element within the riser. The device disclosed in the reference provides a more uniform vapor concentration profile to the exchange bed above the distributor tray, but does not address the problem of improper mixing for liquid redistribution.

#### Objects of the Invention

[0011] It is therefore an object of the invention to provide uniform redistribution of liquid to a distributor between two liquid-vapor contacting zones without the use of a collector.

[0012] It is a further object of the invention to provide uniform redistribution of liquid by using a cost effective, simply constructed baffle suspended above a distributor.

[0013] A still further object of this invention to provide such uniform redistribution of liquid by the use of a baffle suspended above the floor of the distributor which causes a liquid flow to converge and mix as it flows through an open space in the baffle and disperses below the baffle.

#### Summary of the Invention

[0014] This invention is a distributor arrangement for a liquid-vapor contacting column as defined in claim 1 and a method for contacting liquid and vapor in a liquid-vapor contacting column as defined in claim 10.

[0015] This invention comprises a baffle suspended above a distributor in a liquid-vapor contacting column, wherein a liquid flow converges and mixes as it flows through an open space in the baffle and is then dispersed to the distributor below.

[0016] In a preferred embodiment of the invention, the open space in the baffle is a centrally located circular hole fitted with a mixing device to enhance mixing.

#### Brief Description of the Drawings

[0017] Other objects, features and advantages will occur to those skilled in the art from the following description of preferred embodiments and accompanying drawings, in which:

Fig. 1 is a schematic side view of an embodiment of the invention utilizing a distributor with cylindrical gas risers which protrude through a baffle having a centrally located circular open space;

Fig. 2 is a diagram of a preferred embodiment of the invention having a mixer located in the centrally located circular open space;

Fig. 3 is a top sectional view along line A-A of Fig. 1; Fig. 4 is a diagram of yet another embodiment of the invention with a weir attached to a baffle having a central circular open space;

Fig. 5 shows an embodiment of the invention wherein two baffles are used, a baffle with peripheral open space on the bottom and a baffle with central open space on the top; and

Fig. 6 also shows an embodiment with two baffles, a baffle with central open space at the bottom and a baffle with peripheral open space at the top.

#### Detailed Description of the Invention

[0018] This invention may be accomplished by positioning a baffle between a distributor and a liquid-vapor contacting zone. The baffle is suspended at a sufficient height from the distributor floor to allow flow velocities, as the liquid flow expands underneath the baffle, to be such that the associated head required to drive the flow is small relative to the liquid held up on the distributor. This promotes uniform flow across the distributor and thus, prevents the flowrate of liquid, leaving each perforation in the distributor floor, from varying with distance from the open space in the baffle.

[0019] The maximum height above the distributor for the location of the baffle is limited to the maximum height of the standing liquid above the distributor. Thus, depending on column design, the height of the baffle above the distributor is from about 2.54 cm to about 38.1 cm (about 1 inch to about 15 inches).

[0020] The baffle extends over the entire cross section of the distributor. Therefore, all liquid, falling from the packing in the liquid-vapor contacting zone above, is collected on the baffle. At least one open space in the baffle allows the liquid to converge, flow through, and then expand as it disperses onto the distributor below, with a consequent improvement in mixing and a dampening of inertial effects. The open space is sized and positioned so that liquid falling at any point on the baffle, from the packing above, will flow in a direction towards the open space. More than one opening in the baffle may comprise the open space but the openings should be located in a localized area to cause the liquid to converge and mix.

[0021] The liquid mixes while flowing along to the open space and becomes substantially uniform as the flow converges to pass through the open space. Since the open space in the baffle provides the only flow path for the liquid, and since the baffle extends over essentially the entire cross section of the distributor, all of the liquid flow from the packing above meets and mixes as the liquid flow converges to flow through the open space.

[0022] Typically, the baffle is submerged within the standing liquid held up on the distributor but when the liquid level is low the baffle may be completely or partially emergent. Having an open space in the baffle, for

liquid to flow through, does not significantly increase the liquid head on the distributor.

[0023] In order to maintain the liquid head at the level it was without a baffle, the cross sectional area of the open space is greater than the total area of the perforations in the distributor floor, but is considerably less than the column cross sectional area. The ratio of the cross sectional area of the open space in the baffle to the total open area of the perforations in the distributor floor, is preferably between about 1.1:1 to about 150:1. More preferably the ratio is in the range of about 3:1 to about 20:1. Increasing the ratio reduces the radial velocity of liquid flow over the distributor but also reduces the efficacy of mixing. It is also preferred that the open space of the baffle be highly localized across the column cross section such that liquid from a broad region converges to the open space.

[0024] The invention would accomplish similar performance characteristics as when a collector is used in combination with a distributor. A collector with its risers and downcomers is replaced by a baffle made of sheet metal with holes cut in it to fit over the vapor risers of the distributor. This simple construction for a baffle would not require increased column height as with a collector. As a result, the invention also offers the benefit of a significantly reduced capital cost. The invention may also be employed where a liquid-containing feed is introduced to the liquid-vapor contacting column, above the liquid level on the distributor. In summary, the present invention affords the following advantages: 1) reduction in required column height, 2) ease of installation, 3) reduced capital cost, and 4) improved liquid distribution.

[0025] An embodiment of the invention, suitable for air separation processes, is shown in Fig. 1. The inner surface 17 of a liquid-vapor contact column wall houses a distributor and a baffle 11 located between two liquid-vapor contacting zones 1. The distributor consists of a perforated floor 3 and vapor risers 16 topped with "hats" 5. A baffle 11 is located at an elevation 12 from the distributor floor 3 and is essentially sealed around the periphery 15 and to gas risers 16 that extend through it. An open space in the form of a circular hole 13 is located in the center of the baffle 11. It should be noted that with some gas riser layouts a central hole may not be possible. In such cases, the hole should be located as close to the center as practically possible.

[0026] Liquid flows from the liquid-vapor contacting zone 1 above, to the level of the liquid held up on the distributor 3, above the baffle 11. All liquid above the baffle 11 flows in the direction of the arrows towards the hole 13. As the liquid flow converges and passes through the hole 13, it is well mixed and spreads out as it reaches the distributor floor 3 below. The hole 13 is large enough so that it does not contribute significantly to the head of liquid on the distributor. Liquid builds on the distributor floor to a level at which the rate of liquid flowing out through the perforations is equal to that fall-

ing from the liquid-vapor contacting zone 1 above.

[0027] Fig. 2 shows a preferred embodiment of the invention that includes a mixing device 9 within a centrally located open space. The mixing device 9 should be located so as not to interfere with flow through the perforations in the distributor floor directly beneath it and should not require a significant head to drive a liquid flow through it. This mixing device may be a module of structured packing or more preferably a commercially sold mixing device, such as a static mixer. Koch Engineering Company, Inc. is a supplier of suitable static mixers with no moving parts, comprising a series of rigid elements placed lengthwise in a pipe. Intersecting chambers, formed by these elements, split, rearrange and recombine liquid streams until one homogenous stream exists.

[0028] The preferred embodiment of Fig. 2 may also be used with a liquid feed or a liquid-containing feed, (i.e. feed may be a mixture of gas and liquid but at least part liquid). The baffle arrangement of the invention ensures proper mixing of the liquid-containing feed with the liquid emanating from the packing above and also dissipates inertial forces associated with a localized feed source, preserving distribution quality.

[0029] Fig. 3 shows the plan view from section A-A of Fig. 1. This view shows the baffle 11, the "hats" 5 of a plurality of circular risers 16, and an open space 13 in the center. Though Fig. 2 only shows two circular risers 16 covered by hats 5, several vapor risers are shown for demonstration in this view. The open space is shown to be circular, however, in practice the shape of the open space may be varied to maximize mixing efficiency. For example, a rectangular slot may be used.

[0030] As in the embodiment shown in Fig. 4, the baffle 611 may have a weir 688, with a substantially solid wall. The weir forms a passage 622 surrounding the open space 613 in the baffle 611, through which the liquid from the packing must flow after flowing over the top of the weir 688. With a weir, the liquid level is at a level that is higher than it normally would be in the absence of the weir, either during turndown conditions or over the entire range of operation. Such a weir can convert the potential energy associated with the liquid into mixing. By having this weir mounted over the central space of the baffle, it may be designed so that there is only a slight variation in the amount of liquid held up from maximum to minimum flow. The weir may have orifices in its wall to allow liquid to enter laterally and promote mixing.

[0031] Figs. 5 and 6 are embodiments of the invention where more than one baffle is used. The arrangement of Fig. 5 with a top baffle having a central open space and a bottom baffle having a peripheral open space, works well at high and intermediate flows but poorly at low flows where the top baffle is not submerged.

[0032] In Fig. 6, a top baffle having a peripheral opening and a bottom baffle with a central hole mixes well at all flows.

[0033] The arrangement according to Figs. 1 and 2 was tested at a 22.7cm (9 inch) maximum liquid depth

and a 5.1 cm (2 inch) minimum liquid depth.

[0034] Tests were performed on a distributor with the following characteristics:

Distributor diameter = 1.04m (41 inch). 5  
 Baffle elevation = 5.1cm (2 inch.)  
 Hole location = centered and circular  
 Diameter of hole = 10.2cm (4 inch)  
 Open space ratio\* = 5  
 Mixing device = static mixing device 10

\* Open space ratio = ratio of cross sectional area of open space or hole in baffle to total cross sectional area of open space or perforations in distributor floor. 15

[0035] The baffle tested was made of an aluminum sheet and sealed with tape. In practice, either welding or sealant may be employed to seal the baffle.

[0036] This arrangement was tested using point source dye trace tests, where dye was injected in the liquid above the distributor and the liquid at the underside of the distributor was observed for coloration as it poured through the perforations in the distributor floor. The result was substantially uniform mixing regardless of where the point source was located above the distributor. This result was in contrast to the result achieved when no baffle was used. In the latter case, less than 1/4 of the distributor pour points showed observable discoloration for each point source dye trace test. Even without a mixing element, in testing, a marked improvement was observed using the distributor in conjunction with the baffle of the invention with a central open space. 20

[0037] Better results have been achieved when the baffle is sealed leak tight around the gas risers, and the periphery of the baffle has a central opening. However, it is not absolutely necessary to have a leak-tight seal for the invention to work. Some small drain holes in the distributor may be required to release entrained vapor. 25

[0038] Specific features of the invention are shown in one or more of the drawings for convenience only, as each feature may be combined with other features in accordance with the invention. Alternative embodiments will be recognized by those skilled in the art and are intended to be included within the scope of the claims. 30

## Claims

1. A distributor arrangement for a liquid-vapor contacting column having at least two vertically spaced liquid-vapor contacting sections including a lower liquid-vapor contacting section and an upper liquid-vapor contacting section, said distributor arrangement comprising: 35

a) a distributor being adapted to be situated be-

tween the liquid-vapor contacting sections and having a floor (3) with perforations for distributing liquid to said lower liquid-vapor contacting section and vapor risers (16, 416) for distributing vapor to said upper liquid-vapor contacting section; and

b) a baffle (11, 411, 611) made of sheet metal with holes cut in it to fit over and extend around said vapor risers, said baffle being suspended above the distributor floor (3) and extending across the entire cross section of the distributor except for an open space substantially centrally located within the baffle and formed by a single opening (13, 418, 613) or a plurality of openings located in a localized area, said open space causing all of the liquid from said upper liquid-vapor contacting section to meet and mix as the liquid flow converges to flow through the open space before dispersing said liquid onto said distributor, said vapor risers extending through said holes in said baffle and being sealed around. 40

2. The distributor arrangement of claims 1 wherein the said open space is formed by a single opening (13, 418, 613). 45

3. The distributor arrangement of claim 2 further comprising a mixing device (9) situated within said open space (13, 418, 613). 50

4. The distributor arrangement of claim 1 wherein the ratio of the cross sectional area of said open space (13, 418, 613) in said baffle to the cross sectional area of the perforations in the distributor is in the range of about 1.1:1 to about 150:1. 55

5. The distributor arrangement of claim 1 further comprising a second baffle such that one of said baffles is suspended above the other of said baffles and the open space in one of said baffles is located in a position that is not aligned with the open space in the other of said baffles. 60

6. The distributor arrangement of claim 1 further comprising a weir (688) surrounding said open space (613) in said baffle (611) and forming a passage (622), such that liquid must flow over the weir and down through the passage formed by the weir before expanding on the underside of said baffle, resulting in improved mixing. 65

7. A liquid-vapor contacting column having at least two vertically spaced liquid-vapor contacting sections including a lower liquid-vapor contacting section and an upper liquid-vapor contacting section comprising a liquid distributor arrangement as defined in any one of the preceding claims which is situated 70

between the liquid-vapor contacting sections.

8. The liquid-vapor contacting column of claim 7 comprising a wall with an inner surface (17), wherein said baffle (11, 611) is sealingly connected to the inner surface (17) of said liquid-vapor contacting column.

9. The liquid-vapor contacting column of claim 7 wherein said open space (418) is peripherally located between said baffle (411) and said inner surface (17) such that liquid flows to the periphery of the baffle where it converges and mixes as it passes through the open space.

10. A method for counter-currently contacting liquid and vapor in a liquid-vapor contacting column having at least two liquid-vapor contacting zones, comprising:

collecting all of the liquid flow from an upper liquid-vapor contacting zone onto a baffle located between the upper liquid-vapor contacting zone and a distributor, said distributor having a floor with perforations for distributing liquid to a lower liquid-vapor contacting zone and vapor risers for distributing vapor to said upper liquid-vapor contacting zone said baffle extending over the entire cross section of the distributor except for an open space located substantially centrally within the baffle and formed by a single opening or a plurality of openings located in a localized area, said baffle having apertures through which said vapor risers extend and are sealed around, converging the entire collected liquid flow in said open space so that all of the liquid flow meets and mixes as the liquid flow converges to flow through said open space, resulting in substantially uniform mixing of the liquid flow; and dispersing the substantially uniformly mixed liquid flow onto the distributor below while passing vapor through said vapor risers to said upper liquid-vapor contacting zone.

11. The method of claim 10 wherein the ratio of the cross sectional area of the open space in said baffle to the cross sectional area of the perforations in the distributor is selected to be in the range of about 1.1:1 to about 150:1.

12. The method of claim 10 or 11 further comprising passing said collected liquid flow through a mixing device situated within said open space.

13. The method of claim 10, wherein a liquid-containing feed is introduced to the liquid-vapor contacting col-

umn at a location between the baffle and the liquid-vapor contacting zone above.

## 5 Patentprüfungen

1. Verteileranordnung für eine Flüssigkeits/Dampf-Kontaktkolonne mit mindestens zwei vertikal in Abstand angeordneten Flüssigkeits/Dampf-Kontaktabschnitten, die einen unteren Flüssigkeits/Dampf-Kontaktabschnitt und einen oberen Flüssigkeits/Dampf-Kontaktabschnitt umfassen, wobei die Verteileranordnung versehen ist mit:

(a) einem Verteiler, der dafür ausgelegt ist, zwischen den Flüssigkeits/Dampf-Kontaktabschnitten angeordnet zu werden und der einen Boden (3) mit Perforationen zum Verteilen von Flüssigkeit zu dem oberen Flüssigkeits/Dampf-Kontaktabschnitt sowie Dampfsteigrohre (16, 416) zum Verteilen von Dampf zu dem oberen Flüssigkeits/Dampf-Kontaktabschnitt aufweist; und

(b) einem Leitblech (11, 411, 611), das aus Metallblech gefertigt ist, in welches Ausschnitte geschnitten wurden, die über die Dampfsteigrohre passen und sich um diese erstrecken, wobei das Leitblech oberhalb des Verteilerbodens (3) aufgehängt ist und sich über den Querschnitt des Verteilers mit Ausnahme eines im wesentlichen zentral innerhalb des Leitblechs angeordneten offenen Raumes erstreckt, der von einer einzelnen Öffnung (13, 418, 613) oder einer Mehrzahl von Öffnungen, die in einem begrenzten Bereich angeordnet sind, gebildet ist, wobei der offene Raum bewirkt, dass die gesamte Flüssigkeit von dem oberen Flüssigkeits/Dampf-Kontaktabschnitt zusammenläuft und sich mischt, wenn der Flüssigkeitsstrom beim Durchtritt durch den offenen Raum konvergiert, bevor die Flüssigkeit auf den Verteiler dispergiert wird, wobei sich die Dampfsteigrohre durch die Öffnungen in dem Leitblech erstrecken und rundherum abgedichtet sind.

2. Verteileranordnung nach Anspruch 1, wobei der offene Raum von einer einzelnen Öffnung (13, 418, 613) gebildet ist.

3. Verteileranordnung nach Anspruch 2, ferner versehen mit einer Mischvorrichtung (9), die in dem offenen Raum (13, 418, 613) angeordnet ist.

4. Verteileranordnung nach Anspruch 1, wobei das Verhältnis der Querschnittsfläche des offenen Raumes (13, 418, 613) in dem Leitblech zu der Quer-

schnittsfläche der Perforationen in dem Verteiler im Bereich von etwa 1,1:1 bis etwa 150:1 liegt.

5. Verteileranordnung nach Anspruch 1, ferner versehen mit einem zweiten Leitblech, wobei in es d r Leitbleche oberhalb des and r n d r Leitbleche aufgehängt ist und der offene Raum in einem der Leitbleche in einer Position angeordnet ist, die nicht zu dem offenen Raum in dem anderen der Leitbleche ausgerichtet ist. 5  
10
6. Verteileranordnung nach Anspruch 1, ferner versehen mit einem Wehr (688), welches den offenen Raum (613) in dem Leitblech (611) umgibt und einen Durchlass (622) bildet, so dass Flüssigkeit über das Wehr und nach unten durch den von dem Wehr gebildeten Durchlass fließen muss, bevor sie sich an der Unterseite des Leitbleches ausbreitet, was zu einem verbesserten Mischen führt. 15  
20
7. Flüssigkeits/Dampf-Kontaktkolonne mit mindestens zwei vertikal in Abstand angeordneten Flüssigkeits/Dampf-Kontaktabschnitten, die einen unteren Flüssigkeits/Dampf-Kontaktabschnitt und einen oberen Flüssigkeits/Dampf-Kontaktabschnitt umfassen, versehen mit einer Flüssigkeitsverteileranordnung gemäß einem der vorhergehenden Ansprüche, die zwischen den Flüssigkeits/Dampfkontaktabschnitten angeordnet ist. 25  
30
8. Flüssigkeits/Dampf-Kontaktkolonne nach Anspruch 7, versehen mit einer Wand mit einer Innenfläche (17), wobei das Leitblech (11, 611) dichtend mit der Innenfläche (17) der Flüssigkeits/Dampf-Kontaktkolonne verbunden ist. 35
9. Flüssigkeits/Dampf-Kontaktkolonne nach Anspruch 7, wobei der offene Raum (418) in Umfangsrichtung zwischen dem Leitblech (411) und der Innenfläche (17) angeordnet ist, so dass Flüssigkeit zu dem Umfang des Leitblechs strömt, wo sie beim Passieren des offenen Raumes konvergiert und sich mischt. 40
10. Verfahren, um Flüssigkeit und Dampf im Gegenstrom in einer Flüssigkeits/Dampf-Kontaktkolonne in Kontakt zu bringen, die mindestens zwei Flüssigkeits/Dampf-Kontaktzonen aufweist, wobei im Zuge des Verfahrens: 45

der gesamte Flüssigkeitsstrom von einer oberen Flüssigkeits/Dampf-Kontaktzone auf einem Leitblech gesammelt wird, welches zwischen der oberen Flüssigkeits/Dampf-Kontaktzone und in m Verteiler angeordnet ist, wobei der Verteiler einen Boden mit Perforationen zum Verteilen von Flüssigkeit auf ein unter Flüssigkeits/Dampf-Kontaktzone sowie Dampf-

steigrohre zum Verteilen von Dampf zu der oberen Flüssigkeits/Dampf-Kontaktzone aufweist, wobei sich das Leitblech über den gesamten Querschnitt des Verteilers mit Ausnahme eines im wesentlichen zentral innerhalb des Leitbleches angeordneten offenen Raumes erstreckt, der von einer einzelnen Öffnung oder einer Mehrzahl von Öffnungen, die in einem begrenzten Bereich angeordnet sind, gebildet ist, wobei das Leitblech Öffnungen aufweist, durch welche sich die Dampfsteigrohre erstrecken und rundherum abgedichtet sind,

der gesamte gesammelte Flüssigkeitsstrom in dem offenen Raum konvergiert wird, so dass sich der gesamte Flüssigkeitsstrom trifft und mischt, wenn der Flüssigkeitsstrom konvergiert, um durch den offenen Raum zu fließen, was zu einem im wesentlichen gleichförmigen Mischen des Flüssigkeitsstromes führt; und

der im wesentlichen gleichförmig gemischte Flüssigkeitsstrom auf den darunter liegenden Verteiler dispergiert wird, während Dampf durch die Dampfsteigrohre zu der oberen Flüssigkeits/Dampf-Kontaktzone geleitet wird.

11. Verfahren nach Anspruch 10, bei welchem das Verhältnis der Querschnittsfläche des offenen Raumes in dem Leitblech zu der Querschnittsfläche der Perforationen in dem Verteiler so gewählt ist, dass es im Bereich von etwa 1,1:1 bis etwa 150:1 liegt.
12. Verfahren nach Anspruch 10 oder 11, bei welchem ferner der gesammelte Flüssigkeitsstrom durch eine in dem offenen Raum angeordnete Mischvorrichtung geleitet wird.
13. Verfahren nach Anspruch 10, bei welchem ein Flüssigkeit enthaltender Einsatz in die Flüssigkeits/Dampf-Kontaktkolonne an einer Stelle zwischen dem Leitblech und der darüber liegenden Flüssigkeits/Dampf-Kontaktzone eingeleitet wird.

## Revendications

1. Agencement de distributeur pour une colonne de mise en contact d'un liquide et d'une vapeur ayant au moins deux sections espacées verticalement de mise en contact d'un liquide et d'une vapeur comprenant une section inférieure de mise en contact d'un liquide et d'une vapeur et une section supérieure de mise en contact d'un liquide et d'une vapeur, ledit agencement de distributeur comportant :

a) un distributeur conçu pour être situé entre les sections de mise en contact d'un liquide et

- d'une vapeur et ayant un plancher (3) présentant des perforations pour distribuer un liquide à ladite section inférieure de mise en contact d'un liquide et d'une vapeur et des colonnes montantes (16, 416) de vapeur pour distribuer de la vapeur à ladite section supérieure de mise en contact d'un liquide et d'une vapeur ; et
- b) un déflecteur (11, 411, 611) formé d'une feuille de métal dans laquelle des trous sont découpés pour s'ajuster sur lesdites, et s'étendre autour desdites, colonnes montantes de vapeur, ladite chicane étant suspendue au-dessus du plancher (3) du distributeur et s'étendant sur toute la section transversale du distributeur à l'exception d'un espace ouvert, situé sensiblement centralement dans le déflecteur et formé par une seule ouverture (13, 418, 613) ou par plusieurs ouvertures placées dans une zone localisée, ledit espace ouvert amenant la totalité du liquide provenant de ladite section supérieure de mise en contact d'un liquide et d'une vapeur à se rejoindre et se mélanger en même temps que l'écoulement de liquide converge pour s'écouler à travers l'espace ouvert avant de disperser ledit liquide sur ledit distributeur, lesdites colonnes montantes de vapeur s'étendant à travers lesdits trous dans ladite chicane et étant scellées de façon étanche sur leur pourtour.
2. Agencement de distributeur selon la revendication 1, dans lequel ledit espace ouvert est formé par une seule ouverture (13, 418, 613).
  3. Agencement de distributeur selon la revendication 2, comportant en outre un dispositif mélangeur (9) situé à l'intérieur dudit espace ouvert (13, 418, 613).
  4. Agencement de distributeur selon la revendication 1, dans lequel le rapport de l'aire de la section transversale dudit espace ouvert (13, 418, 613) dans ledit déflecteur à l'aire de la section transversale des perforations dans le distributeur est compris dans la plage d'environ 1,1:1 à environ 150:1.
  5. Agencement de distributeur selon la revendication 1, comportant en outre un second déflecteur tel que l'un desdits déflecteurs est suspendu au-dessus de l'autre desdits déflecteurs et que l'espace ouvert dans l'un desdits déflecteurs est placé dans une position qui n'est pas alignée avec l'espace ouvert dans l'autre desdits déflecteurs.
  6. Agencement de distributeur selon la revendication 1, comportant en outre un déversoir (688) entourant ledit espace ouvert (613) dans ledit déflecteur (611) et formant un passage (622), afin qu'un liquide doive s'écouler par-dessus le déversoir et descendre dans le passage formé par le déversoir avant de s'expanser sur le côté inférieur dudit déflecteur, ce qui aboutit à un mélange amélioré.
  7. Colonne de mise en contact d'un liquide et d'une vapeur ayant au moins deux sections espacées verticalement de mise en contact d'un liquide et d'une vapeur comprenant une section inférieure de mise en contact d'un liquide et d'une vapeur et une section supérieure de mise en contact d'un liquide et d'une vapeur, comportant un agencement de distributeur de liquide tel que défini dans l'une quelconque des revendications précédentes, qui est situé entre les sections de mise en contact d'un liquide et d'une vapeur.
  8. Colonne de mise en contact d'un liquide et d'une vapeur selon la revendication 7, comportant une paroi ayant une surface intérieure (17), dans laquelle ledit déflecteur (11, 611) est relié de façon étanche à la surface intérieure (17) de ladite colonne de mise en contact d'un liquide et d'une vapeur.
  9. Colonne de mise en contact d'un liquide et d'une vapeur selon la revendication 7, dans lequel ledit espace ouvert (418) est placé de façon périphérique entre ledit déflecteur (411) et ladite surface intérieure (17) afin qu'un liquide s'écoule vers la périphérie du déflecteur où il converge et se mélange en passant à travers l'espace ouvert.
  10. Procédé de mise en contact à contre-courant d'un liquide et d'une vapeur dans une colonne de mise en contact d'un liquide et d'une vapeur ayant au moins deux zones de mise en contact d'un liquide et d'une vapeur, comprenant :
 

la collecte de la totalité de l'écoulement de liquide provenant d'une zone supérieure de mise en contact d'un liquide et d'une vapeur sur un déflecteur placé entre la zone supérieure de mise en contact d'un liquide et d'une vapeur et un distributeur, ledit distributeur ayant un plancher présentant des perforations pour distribuer un liquide vers une zone inférieure de mise en contact d'un liquide et d'une vapeur et des colonnes montantes de vapeur pour distribuer une vapeur vers ladite zone supérieure de mise en contact d'un liquide et d'une vapeur, ledit déflecteur s'étendant sur toute la section transversale du distributeur à l'exception d'un espace ouvert placé sensiblement centralement dans le déflecteur et formé par une seule ouverture ou par plusieurs ouvertures situées dans une zone localisée, ledit déflecteur ayant des trous à travers lesquels lesdites colonnes montantes de vapeur s'étendent et sont scellées de façon étanche sur leur pourtour,

la convergence de l'écoulement collecté entier de liquide dans ledit espace ouvert afin que la totalité de l'écoulement de liquide se rejoigne et se mélange pendant que l'écoulement de liquide converge pour s'écouler à travers ledit espace ouvert, ce qui aboutit à un mélange sensiblement uniforme de l'écoulement de liquide ; et

la dispersion de l'écoulement de liquide mélangé de façon sensiblement uniforme sur le distributeur situé en dessous en même temps que de la vapeur passe dans lesdites colonnes montantes de vapeur vers ladite zone supérieure de mise en contact d'un liquide et d'une vapeur.

11. Procédé selon la revendication 10, dans lequel le rapport de l'aire de la section transversale de l'espace ouvert dans ledit déflecteur à l'aire de la section transversale des perforations dans le distributeur est choisi de façon à être compris dans la plage d'environ 1,1:1 à environ 150:1.
12. Procédé selon la revendication 10 ou 11, comprenant en outre le passage dudit écoulement de liquide collecté à travers un dispositif mélangeur situé dans ledit espace ouvert.
13. Procédé selon la revendication 10, dans lequel une charge contenant un liquide est introduite dans la colonne de mise en contact d'un liquide et d'une vapeur en un emplacement situé entre le déflecteur et la zone, situé au-dessus, de mise en contact d'un liquide et d'une vapeur.
